The interpreter pattern I. Expression trees

Main idea: Represent a program as a data structure, run it later

Example: a simple DSL for complex numbers

```
val a = "1+2*i".toComplex
val b = a * "3-4*i".toComplex
b.conj
Conj(
Mul(
Str("1+2*i"), Str("3-4*i")
))
```

• Unevaluated operations Str, Mul, Conj are defined as case classes:

```
sealed trait Prg
case class Str(s: String) extends Prg
case class Mul(p1: Prg, p2: Prg) extends Prg
case class Conj(p: Prg) extends Prg
```

• An interpreter will "run" the program and return a complex number

```
def run(prg: Prg): (Double, Double) = ...
```

- Benefits: programs are data, can compose & transform before running
- Shortcomings: this DSL works only with simple expressions
 - Cannot represent variable binding and conditional computations
 - ► Cannot use any non-DSL code (e.g. a numerical algorithms library)

The interpreter pattern II. Variable binding

A DSL with variable binding and conditional computations

- Example: imperative API for reading and writing files
 - ▶ Need to bind a *non-DSL variable* to a value computed by DSL
 - ▶ Later, need to use that non-DSL variable in DSL expressions
 - ▶ The rest of the DSL program is a (Scala) function of that variable

```
val p = path("/file")
val str: String = read(p)
if (str.nonEmpty)
  read(path(str))
else "Error: empty path"

Bind(
  Read(Path(Literal("/file"))),
  { str \( \Rightarrow / / \) read value 'str'
  if (str.nonEmpty)
      Read(Path(Literal(str)))
      else Literal("Error: empty path")
})
```

Unevaluated operations are implemented via case classes:

```
sealed trait Prg
case class Bind(p: Prg, f: String ⇒ Prg) extends Prg
case class Literal(s: String) extends Prg
case class Path(s: Prg) extends Prg
case class Read(p: Prg) extends Prg
...
```

• Interpreter: def run(prg: Prg): String = ...

The interpreter pattern III. Type safety

- So far, the DSL has no type safety: every value is a Prg
- We want to avoid errors, e.g. Read(Read(...)) should not compile
- Let Prg[A] denote a DSL program returning value of type A when run:

```
sealed trait Prg[A]
case class Bind(p: Prg[String], f: String ⇒ Prg[String])
  extends Prg[String]
case class Literal(s: String) extends Prg[String]
case class Path(s: Prg[String]) extends Prg[nio.file.Path]
case class Read(p: Prg[nio.file.Path]) extends Prg[String]
```

- Interpreter: def run(prg: Prg[String]): String = ...
- Our example DSL program is type-safe now:

```
val prg: Prg[String] = Bind(
  Read(Path(Literal("/file"))),
      { str: String ⇒
      if (str.nonEmpty)
        Read(Path(Literal(str)))
      else Literal("Error: empty path")
  })
```

The interpreter pattern IV. Cleaning up the DSL

Our DSL so far:

```
sealed trait Prg[A]
case class Bind(p: Prg[String], f: String ⇒ Prg[String])
  extends Prg[String]
case class Literal(s: String) extends Prg[String]
case class Path(s: Prg[String]) extends Prg[nio.file.Path]
case class Read(p: Prg[nio.file.Path]) extends Prg[String]
```

Problems with this DSL:

- Cannot use Read(p: nio.file.Path), only Read(p: Prg[nio.file.Path])
- Cannot bind variables or return values other than String

To fix these problems, make Literal a fully parameterized operation and replace Prg[A] by A in case class arguments

```
sealed trait Prg[A]
case class Bind[A, B](p: Prg[A], f: A⇒Prg[B]) extends Prg[B]
case class Literal[A](a: A) extends Prg[A]
case class Path(s: String) extends Prg[nio.file.Path]
case class Read(p: nio.file.Path) extends Prg[String]
```

• The type signatures of Bind and Literal are like flatMap and pure

The interpreter pattern V. Define Monad-like methods

• We can actually define the methods map, flatMap, pure:

```
sealed trait Prg[A] {
  def flatMap[B](f: A \Rightarrow Prg[B]): Prg[B] = Bind(this, f)
  def map[B](f: A \Rightarrow B): Prg[B] = flatMap(this, f andThen Prg.pure)
object Prg { def pure[A](a: A): Prg[A] = Literal(a) }
```

- These methods don't run anything, only create unevaluated structures
- DSL programs can now be written as functor blocks and composed:

Chapter 10: Free type constructions

```
def readPath(p: String): Prg[String] = for {
    path \leftarrow Path(p)
    str \leftarrow Read(path)
  } yield str
  val prg: Prg[String] = for {
    str \( \text{readPath("/file")} \)
    result ← if (str.nonEmpty)
         readPath(str)
      else Prg.pure("Error: empty path")
  } yield result
Interpreter: def run[A](prg: Prg[A]): A = ...
```

6 / 21

The interpreter pattern VI. Refactoring to an abstract DSL

• Write a DSL for complex numbers in a similar way:

```
sealed trait Prg[A] { def flatMap ... } // no code changes case class Bind[A, B] (p: Prg[A], f: A \Rightarrow Prg[B]) extends Prg[B] case class Literal[A](a: A) extends Prg[A] type Complex = (Double, Double) // custom code starts here case class Str(s: String) extends Prg[Complex] case class Mul(c1: Complex, C2: Complex) extends Prg[Complex] case class Conj(c: Complex) extends Prg[Complex]
```

Refactor this DSL to separate common code from custom code:

```
sealed trait DSL[F[_], A] { def flatMap ... } // no code changes type Prg[A] = DSL[F, A] // just for convenience case class Bind[A, B](p: Prg[A], f: A \Rightarrow Prg[B]) extends Prg[B] case class Literal[A](a: A) extends Prg[A] custom operations here
```

Interpreter is parameterized by a "value extractor"
 Ex^F ≡ ∀A. (F^A ⇒ A)
 def run[F[_], A](ex: Ex[F])(prg: DSL[F, A]): A = ...

The interpreter pattern VII. Handling errors

- To handle errors, we want to evaluate DSL[F[_], A] to Either[Err, A]
- Suppose we have a value extractor of type $\operatorname{Ex}^F \equiv \forall A. (F^A \Rightarrow \operatorname{Err} + A)$
- The code of the interpreter is almost unchanged:

```
def run[F[_], A](extract: Ex[F])(prg: DSL[F, A]): Either[Err, A] =
  prg match {
    case b: Bind[F, _, A] ⇒ b match { case Bind(p, f) ⇒
            run(extract)(p).flatMap(f andThen run(extract))
    } // Here, the .flatMap is from Either.
    case Literal(a) ⇒ Right(a) // pure: A ⇒ Err + A
    case Ops(f) ⇒ extract(f)
}
```

- The code of run only uses flatMap and pure from Either
- We can generalize to any other monad M^A instead of Either[Err, A]

The resulting construction:

- Start with an "operations type constructor" F^A (often not a functor)
- Use DSL^{F,A} and interpreter run : $(\forall X.F^X \Rightarrow M^X) \Rightarrow DSL^{F,A} \Rightarrow M^A$
- Create a DSL program prg : DSL F,A and an extractor ex $^X: F^X \Rightarrow M^X$
- Run the program with the extractor: run (ex) (prg); get a value M^A

The interpreter pattern VIII. Monadic DSLs: summary

- Begin with a number of operations, which are typically functions of fixed known types such as $A_1 \Rightarrow B_1$, $A_2 \Rightarrow B_2$ etc.
- Define a type constructor (typically not a functor) encapsulating all the operations as case classes, with or without type parameters

```
sealed trait F[A] case class Op1(a1: A1) extends F[B1] case class Op2(a1: A2) extends F[B2]
```

- Use DSL[F,A] with this F to write monadic DSL programs prg: DSL[F,A]
- Choose a target monad M[A] and implement an extractor $ex:F[A] \Rightarrow M[A]$
- Run the program with the extractor, val res: M[A] = run(ex)(prg)

Further directions (out of scope for this chapter):

- May choose another monad N[A] and use interpreter M[A] ⇒ N[A]
 - ▶ For example, transform into another monadic DSL to optimize, etc.
- Since DSL[F,A] has a monad API, we can use monad transformers on it
- Can combine two or more DSLs in a disjunction: DSL[F \/ G, A]

Monad laws for DSL programs

Monad laws hold for DSL programs only after evaluating them

- Consider the law flm (pure) = id; both functions $DSL^{F,A} \Rightarrow DSL^{F,A}$
- ullet Apply both sides to some prg : $DSL^{F,A}$ and get the new value

```
prg.flatMap(pure) == Bind(prg, a ⇒ Literal(a))
```

- This new value is not equal to prg, so this monad law fails!
 - Other laws fail as well because operations never reduce anything
- After interpreting this program into a target monad M^A , the law holds:

```
run(ex)(prg).flatMap((a ⇒ Literal(a)) andThen run(ex))
== run(ex)(prg).flatMap(a ⇒ run(ex)(Literal(a))
== run(ex)(prg).flatMap(a ⇒ Right(a))
== run(ex)(prg)
```

- \blacktriangleright Here we have assumed that the laws hold for M^A
- ightharpoonup All other laws also hold after interpreting into a lawful monad M^A

The monad law violations are "not observable"

Free constructions in mathematics: Example I

- \bullet Consider the Russian letter μ (tsè) and the Chinese word 水 (shuï)
- We want to *multiply* ц by 水. Multiply how?
- Say, we want an associative (but noncommutative) product of them
 - ► So we want to define a *semigroup* that *contains* ц and 水 as elements
 - * while we still know nothing about ц and 水
- Consider the set of all *unevaluated expressions* such as ц·水·水·ц·水
 - ► Here $\mathbf{q} \cdot \mathbf{n}$ is different from $\mathbf{n} \cdot \mathbf{q}$ but $(a \cdot b) \cdot c = a \cdot (b \cdot c)$
- ullet All these expressions form a **free semigroup** generated by ц and x
 - ▶ This is the most unrestricted semigroup that contains ц and 水
- Example calculation: (水水)·(ц·水)·ц = 水·水·ц·水·ц

How to represent this as a data type:

- Tree encoding: the full expression tree: $((水,水),(\mathtt{u},水)),\mathtt{u})$
 - ▶ Implement the operation $a \cdot b$ as pair constructor (easy)
- Reduced encoding, as a "smart" structure: List(水,水,ц,水,ц)
 - ▶ Implement $a \cdot b$ by concatenating the lists (more expensive)

Free constructions in mathematics: Example II

- ullet Want to define a product operation for *n*-dimensional vectors: ${f v}_1 \otimes {f v}_2$
- The ⊗ must be linear and distributive (but not commutative):

$$\begin{aligned} u_1 \otimes v_1 + \left(u_2 \otimes v_2 + u_3 \otimes v_3\right) &= \left(u_1 \otimes v_1 + u_2 \otimes v_2\right) + u_3 \otimes v_3 \\ u \otimes \left(a_1 v_1 + a_2 v_2\right) &= a_1 \left(u \otimes v_1\right) + a_2 \left(u \otimes v_2\right) \\ \left(a_1 v_1 + a_2 v_2\right) \otimes u &= a_1 \left(v_1 \otimes u\right) + a_2 \left(v_2 \otimes u\right) \end{aligned}$$

- ▶ We have such a product for 3-dimensional vectors only; ignore that
- Consider unevaluated expressions of the form $\mathbf{u}_1 \otimes \mathbf{v}_1 + \mathbf{u}_2 \otimes \mathbf{v}_2 + ...$
 - A free vector space generated by pairs of vectors
- Impose the equivalence relationships shown above
 - ► The result is known as the **tensor product**
- Tree encoding: full unevaluated expression tree
 - ▶ A list of any number of vector pairs $\sum_i \mathbf{u}_i \otimes \mathbf{v}_i$
- Reduced encoding: a matrix
 - ▶ Reduced encoding requires proof and more complex operations

Worked example: Free semigroup

Implement a free semigroup FSIS generated by two types Int and String

- A value of FSIS can be an Int; it can also be a String
- If x, y are of type FSIS then so is Mul(x, y)

```
sealed trait FSIS // tree encoding: full expression tree
case class Wrap1(x: Int) extends FSIS
case class Wrap2(x: String) extends FSIS
case class Mul(x: FSIS, y: FSIS) extends FSIS
```

- Short type notation: $FSIS \equiv Int + String + FSIS \times FSIS$
- For a semigroup S and given Int $\Rightarrow S$ and String $\Rightarrow S$, map FSIS $\Rightarrow S$
- Simplify and generalize this construction by setting Z = Int + String
- The redundant encoding is $FS^Z = Z + FS^Z \times FS^Z$

```
def mul(x: FS[Z], y: FS[Z]): FS[Z] = Mul(x, y)
def run[S: Semigroup, Z](extract: Z \Rightarrow S): FS[Z] \Rightarrow S = \{ case F(z) \Rightarrow extract(z) case Mul(x, y) \Rightarrow run(extract)(x) \mid + \mid run(extract)(y) \} // Semigroup laws will hold after applying run().
```

- The reduced encoding is $FSR^Z \equiv Z \times List^Z$ (non-empty list of Z's)
 - ▶ Mul(x, y) requires concatenating the lists but run() is faster

Worked example: Free monoid

Implement a free monoid FM[Z] generated by type Z

- A value of FM[Z] can be the empty value; it can also be a Z
- If x, y are of type FM[Z] then so is Mul(x, y)

```
sealed trait FM[Z] // tree encoding
case class Empty[Z]() extends FM[Z]
case class Wrap[Z](z: Z) extends FM[Z]
case class Mul[Z](x: FM[Z], y: FM[Z]) extends FM[Z]
```

- Short type notation: $FM^Z \equiv 1 + Z + FM^Z \times FM^Z$
- For a monoid M and given $Z \Rightarrow M$, map $FM^Z \Rightarrow M$

```
def mul(x: FM[Z], y: FM[Z]): FM[Z] = Mul(x, y)
def run[M: Monoid, Z](extract: Z \Rightarrow M): FM[Z] \Rightarrow M = {
  case Empty() \Rightarrow Monoid[M].empty
  case Wrap(z) \Rightarrow extract(z)
  case Mul(x, y) \Rightarrow run(extract)(x) |+| run(extract)(y)
} // Monoid laws will hold after applying run().
```

- The reduced encoding is $FMR^Z \equiv List^Z$ (list of Z's)
 - ► The multiplication requires concatenating the lists
- Reduced encoding and tree encodings give identical results after run()

Generalize: Universal property and initiality

- Generalize from free monad and free monoid/ semigroup to free typeclass C
- Which typeclass can or cannot be made free

Multiple target instances

Worked example: free functor

Generaize

Worked example: free pointed functor

ullet Also consider the case when we start from a functor F

Worked example: free filterable

Generaiz

Worked example: free applicative

Generaiz

Exercises

Implement a free semigroup generated by a type parameter Z in the tree encoding and in the reduced encoding. Show that the semigroup laws hold for the reduced encoding but not for the tree encoding before interpreting into a lawful semigroup S.
